Executive Summary

This report describes the security analysis that was done as part of a bug bounty program assignment against the domain deribit.com and its subdomains. Using an organised, ethical hacking methodology, the assessment was carried out as part of the IE2062-Web Security module to find and record possible security flaws.

The engagement used a thorough testing methodology, mapping the attack surface first through intensive reconnaissance. This included active vulnerability scanning, service discovery, and subdomain enumeration. Sublist3r, Nmap, Nikto, Nuclei, and SQLmap were among the industry-standard tools used to methodically find security vulnerabilities.

The assessment successfully identified several security-related findings, which were validated and documented with Proof-of-Concept (PoC) evidence

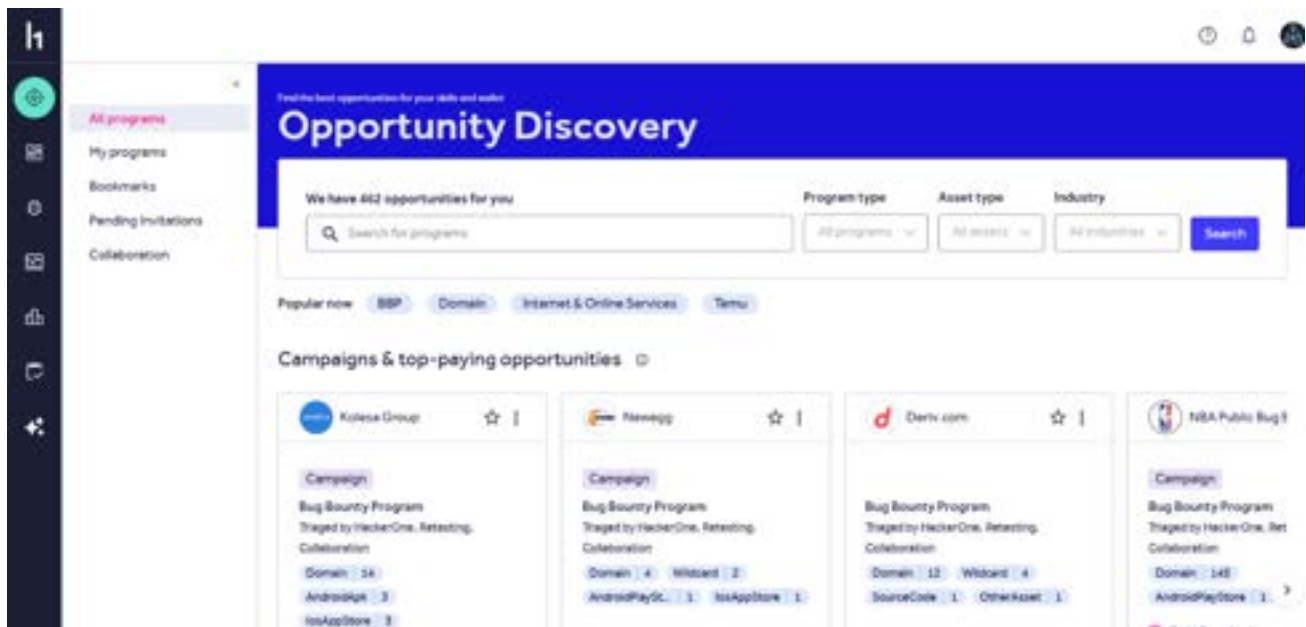

Every result has been grouped according to severity and includes thorough justifications of its possible effects, potential routes of exploitation, and suggested corrective actions. The evaluation comes to the conclusion that although the target's fundamental defences are strong, resolving the configuration and information disclosure problems will improve its security posture by applying the defense-in-depth principle. From preliminary reconnaissance to expert reporting, the procedure offered priceless hands-on experience in contemporary web application security testing.

Methodology

❖ Select a Program and Creating an Account

Before starting my bug bounty assignment I explored many platforms and programs. Among them are Bugcrowd, and HackerOne. To improve my bug-hunting efforts, I researched and evaluated several platforms based on their caller and program offerings. These platforms are well-known in the cybersecurity industry for their strong program frameworks, large readership, and active community of researchers.

In finally, I decided to use HackerOne platform to complete my bug bounty program.

❖ Tools utilized

Reconnaissance / Discovery on the Target

1) Sublist3r

A screenshot of a terminal window showing the Sublist3r tool's interface. At the top, the word 'Sublist3r' is displayed in a large, red, stylized font. Below it, a line of text reads '# Coded By Ahmed Aboul-Ela - @aboul3la'. The main part of the terminal shows a list of search engines being scanned, each preceded by a green '['-]' character. The target domain 'deribit.com' is specified in the first line of the list.

```
Sublist3r
# Coded By Ahmed Aboul-Ela - @aboul3la

[-] Enumerating subdomains now for deribit.com
[-] Searching now in Baidu..
[-] Searching now in Yahoo..
[-] Searching now in Google..
[-] Searching now in Bing..
[-] Searching now in Ask..
[-] Searching now in Netcraft..
[-] Searching now in DNSdumpster..
[-] Searching now in Virustotal..
[-] Searching now in ThreatCrowd..
[-] Searching now in SSL Certificates..
[-] Searching now in PassiveDNS..
```

Sublist3r uses OSINT (Open-Source Intelligence) to quickly scan for subdomains on websites. Python is used for writing, and threading allows for faster execution. This method enhances vulnerability scanning by increasing the number of potential entry sites. It aids hackers and bug bounty hunters in understanding the attack surface. Multiple search engines, such as Google, Yahoo, Bing, and Netcraft, are incorporated. One of its key features is the ability to identify subdomains using third-party APIs and brute-force methods.

2) Httpprobe

```
kali@kali -  
Session Actions Edit View Help  
(kali@kali)-[~]  
$ httpprobe < /home/kali/Documents/BugBounty/Deribit/Deribit.txt > /home/kali/Documents/BugBounty/Deribit/active_deribit.txt
```

Httpprobe is a lightweight, command-line utility that quickly determines which hostnames serve HTTP or HTTPS, making it ideal for filtering large subdomain lists to the subset of live web endpoints. Commonly used immediately after subdomain enumeration, Httpprobe accepts piped input and probes configurable ports, returning only responsive hosts so downstream scanners and manual testing focus on meaningful targets. Its speed and simplicity make it excellent for automation chains (e.g., `subdomains.txt | httpprobe`), but it only checks web protocols and won't detect non-HTTP services. Use conservative concurrency when probing many hosts to avoid accidental load, and always respect program scope and rate limits.

Network & Port Scanning Tools

1) Nmap

```
(kaliⓈkali)-[~]  
$ nmap apt.deribit.com  
Starting Nmap 7.95 ( https://nmap.org ) at 2025-09-24 12:40 EDT  
Nmap scan report for apt.deribit.com (194.28.45.190)  
Host is up (0.017s latency).  
Not shown: 995 filtered tcp ports (no-response)  
PORT      STATE SERVICE  
21/tcp    open  ftp  
80/tcp    open  http  
443/tcp   open  https  
554/tcp   open  rtsp  
1723/tcp  open  pptp  
  
Nmap done: 1 IP address (1 host up) scanned in 21.19 seconds  
  
(kaliⓈkali)-[~]  
$
```

Nmap (Network Mapper) is a powerful, industry-standard network discovery and security-auditing tool used to identify live hosts, open ports, running services, and OS/service versions across networks. Security testers use it early to build an asset inventory and to prioritise which services need deeper inspection; common commands include `-sS` for stealthy TCP scans, `-sV` for service/version detection, and `-p-` to scan all ports. Nmap's scripting engine (NSE) adds automated checks for common issues, while its flexibility supports both single-target reconnaissance and large-scale sweeps. Because it can be noisy and trigger IDS/IPS, always follow program rules, throttle scans, and prefer conservative timing on third-party targets.

Web Vulnerability Scanning

1) Nuclei

```
(kali@kali)-[~]
$ nuclei

  _____
 /  _  _  _  \
|  _ \| | | | | | |
| |_) | | | | |
|  _ \| | | | |
|_| \_|_|_|_|_|
               v3.4.10
      projectdiscovery.io

[INF] nuclei-templates are not installed, installing...
[INF] Successfully installed nuclei-templates at /home/kali/.local/nuclei-templates
[WRN] Found 1 templates with syntax error (use -validate flag for further examination)
[INF] Current nuclei version: v3.4.10 (latest)
[INF] Current nuclei-templates version: v10.2.9 (latest)
[INF] New templates added in latest release: 182
[INF] Templates loaded for current scan: 8497
[INF] Executing 8295 signed templates from projectdiscovery/nuclei-templates
[WRN] Loading 202 unsigned templates for scan. Use with caution.
[INF] Scan completed in 31.860138ms. No results found.

(kali@kali)-[~]
$
```

Nuclei is a fast, customizable vulnerability scanner that uses community-maintained YAML templates to identify misconfigurations, CVEs, exposed panels, and other common security issues across web applications and infrastructure. Unlike traditional automated scanners, Nuclei is lightweight and template-driven, allowing testers to select or craft checks that match their scope and engagement needs. It's often used after reconnaissance and host discovery (e.g., with Sublist3r and Httpprobe) to quickly verify vulnerabilities across many targets. Because it supports automation and concurrency, it can scale well in bug bounty workflows, but testers should apply strict rate limits and avoid destructive templates to comply with rules of engagement and prevent service disruption.

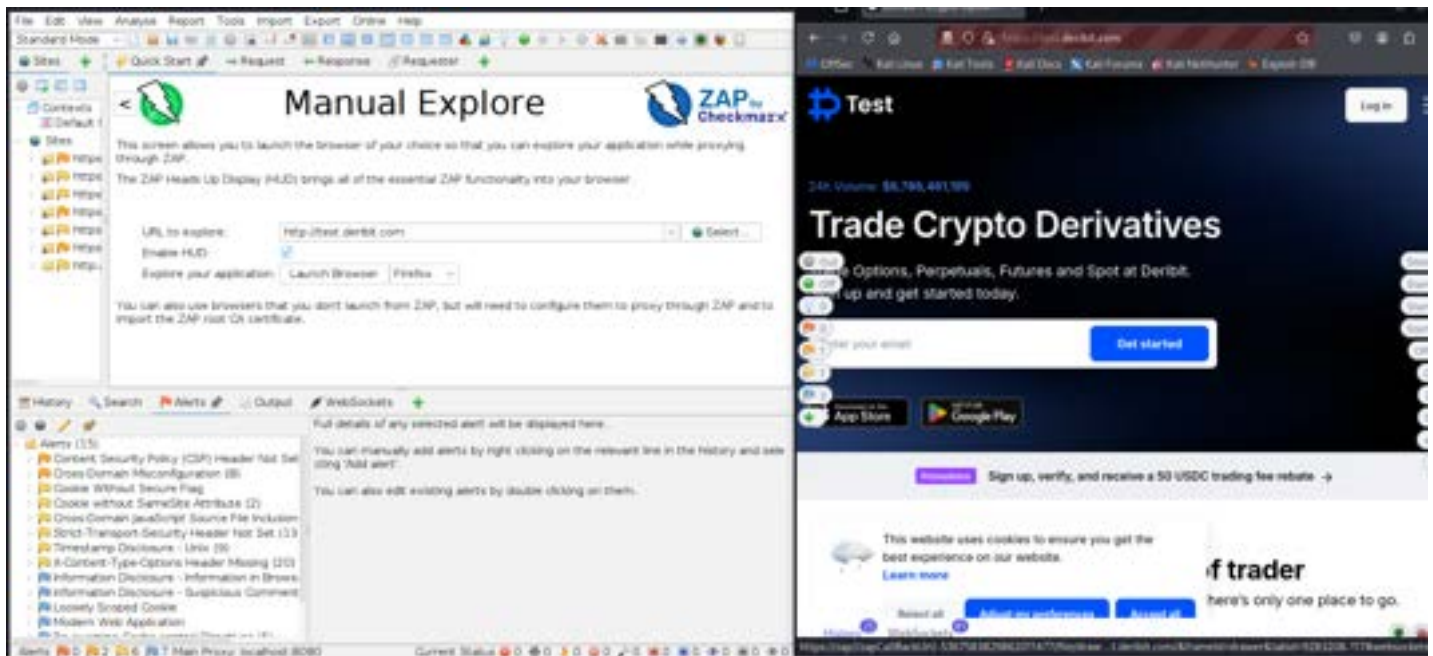

2) Nikto

```
Session Actions Edit View Help
(kali@kali)-[~]
$ sudo apt update
[sudo] password for kali:
Get:1 http://kali.download/kali kali-rolling InRelease [34.0 kB]
Get:2 http://kali.download/kali kali-rolling/main amd64 Packages [21.0 MB]

Get:5 http://kali.download/kali kali-rolling/contrib amd64 Contents (deb) [326 kB]
Get:6 http://kali.download/kali kali-rolling/non-free amd64 Packages [201 kB]
Get:7 http://kali.download/kali kali-rolling/non-free amd64 Contents (deb) [911 kB]
Get:8 http://kali.download/kali kali-rolling/non-free-firmware amd64 Packages [11.3 kB]
Fetched 73.2 MB in 3min 33s (344 kB/s)
388 packages can be upgraded. Run 'apt list --upgradable' to see them.

(kali@kali)-[~]
$ sudo apt install nikto -y
nikto is already the newest version (1:2.5.0+git20230114.90ff645-0kali1).
nikto set to manually installed.
Summary:
Upgrading: 0, Installing: 0, Removing: 0, Not Upgrading: 388
```

Nikto is an open-source web server scanner that probes web servers for dangerous files, misconfigurations, outdated software, and common vulnerabilities by checking against a large database of signatures and test cases. It's useful early in assessments to quickly reveal exposed admin panels, backup files, insecure headers, and known CGI/script issues (example: **nikto -h https://target.example.com**). Nikto is simple and broad in coverage, but it's noisy and can produce false positives, so findings should be manually validated. Because it performs many intrusive checks, limit its use against third-party targets, throttle scan speed, and always follow the program's scope and rules of engagement.

3) OWASP ZAP

OWASP ZAP (Zed Attack Proxy) is a comprehensive, open-source web application security testing tool designed for both automated and manual testing. It functions as an intercepting proxy, allowing testers to capture, modify, and replay HTTP/S traffic, while also providing spidering, fuzzing, and active/passive scanning capabilities. ZAP is ideal for exploring web applications, identifying vulnerabilities such as SQL injection, cross-site scripting (XSS), and broken authentication, and validating findings from other scanners. Its extensible interface supports add-ons and scripting, making it suitable for complex workflows. Testers should use it cautiously on third-party targets, focusing on non-destructive scans and respecting the rules of engagement.

Exploitation / DB Testing

1) SQLmap

```
(kali@kali)-[~]
$ sqlmap -h
```

```
{1.9.9#stable}
https://sqlmap.org
```

Usage: python3 sqlmap [options]

Options:

-h, --help	Show basic help message and exit
-hh	Show advanced help message and exit
--version	Show program's version number and exit
-v VERBOSE	Verbosity level: 0-6 (default 1)

SQLmap is an open-source penetration testing tool designed to automate the detection and exploitation of SQL injection vulnerabilities in web applications. It supports a wide range of database engines, including MySQL, PostgreSQL, Oracle, and SQL Server, and can enumerate databases, extract tables and data, access the file system, and even execute limited commands depending on permissions. SQLmap automates tedious tasks like testing different injection points, encoding techniques, and authentication bypasses, making it highly efficient for security testing. Because it can be intrusive and potentially destructive, testers must use it carefully, only on authorized targets, with non-destructive payloads, and within the program's rules of engagement.

```

Deribit is a cryptocurrency derivatives exchange that primarily trades futures, perpetual contracts, and options for major cryptocurrencies such as Bitcoin (BTC) and Ethereum (ETH).

The provided terminal shows the results of a `whois` lookup performed for the domain `deribit.com`. The query was executed from a Kali Linux machine, and the output reveals the domain's registration details. According to the information, the domain is registered with Name.com, Inc., and it was originally created on January 15, 2014, with an expiration date set for January 15, 2027. The domain's status is currently set to prohibit client-initiated transfers and updates, and its name servers are managed by Cloudflare, specifically `malavika.ns.cloudflare.com` and `vicky.ns.cloudflare.com`, with DNSSEC remaining unsigned. The whois record was last updated by the registry on July 27, 2025, and the information retrieved from the whois database is current as of September 23, 2025.

Eligible subdomains for bug bounty program are given below.

Information gathering phase.

The Information Gathering phase is the first step in the cybersecurity kill chain or penetration testing process. It involves collecting as much information as possible about a target system, organization, or individual before attempting any attacks. The goal is to understand the target's environment so that potential vulnerabilities can be identified.

There are two types of Information Gathering

1) Passive Information Gathering (no direct interaction with target)

- Involves collecting publicly available data without alerting the target.
- Examples:
 - WHOIS lookups (domain info)
 - Google dorking / OSINT (Open-Source Intelligence)
 - Social media analysis (LinkedIn, Facebook, Twitter)
 - Searching breached databases
 - DNS enumeration via public records

2) Active Information Gathering (direct interaction with target)

- Involves probing the target system directly, which may be logged or detected.
- Examples:
 - Port scanning (Nmap)
 - Banner grabbing (service versions)
 - Network mapping (traceroute)
 - Web server fingerprinting (WhatWeb, Wappalyzer)
 - SMB/FTP/SSH enumeration

Identifying active subdomains and their statuses.

Identifying active subdomains means discovering subdomains of a target domain that are currently online and reachable, then checking their status (HTTP/HTTPS response, open ports, service availability, etc.).

Firstly, install Sublist3r in Linux, we can use the below command.

“sudo apt update”

“sudo apt install git python3 python3-pip -y”

```
(kali@kali)-[~]
└─$ sudo apt update
[sudo] password for kali:

Summary:
Upgrading: 0, Installing: 0, Removing: 0, Not Upgrading: 7
```

This repository contains all of the necessary files for installing the application. To download, enter the following command in your shell.

“git clone <https://github.com/aboul3la/Sublist3r.git>”

```
(kali@kali)-[~]
└─$ git clone https://github.com/aboul3la/Sublist3r.git
Cloning into 'Sublist3r'...
remote: Enumerating objects: 383, done.
remote: Total 383 (delta 0), reused 0 (delta 0), pack-reused 383 (from 1)
Receiving objects: 100% (383/383), 1.12 MiB | 3.57 MiB/s, done.
Resolving deltas: 100% (213/213), done.

(kali@kali)-[~]
└─$ cd Sublist3r
```

After downloading the files, proceed to the "Sublist3r" directory and install the necessary documents by entering,

“pip3 install -r requirements.txt “

```

(kali@kali)~$ pip3 install sublist3r
error: externally-managed-environment

This environment is externally managed
To install Python packages system-wide, try apt install
python3-xyz, where xyz is the package you are trying to
install.

If you wish to install a non-Kali-packaged Python package,
create a virtual environment using python3 -m venv path/to/venv.
Then use path/to/venv/bin/python and path/to/venv/bin/pip. Make
sure you have pypyl-venv installed.

If you wish to install a non-Kali-packaged Python application,
it may be easiest to use pipx install xyz, which will manage a
virtual environment for you. Make sure you have pipx installed.

For more information, refer to the following:
* https://www.kali.org/docs/general-use/python3-external-packages/
* /usr/share/doc/python3.13/README.venv

note: If you believe this is a mistake, please contact your Python installation or OS distribution provider. You can override thi
s, at the risk of breaking your Python installation or OS, by passing --break-system-packages.
hint: See PEP 668 for the detailed specification.

(kali@kali)~$

```

I created a .txt file to store the subdomain headers that were initiated via sublist3r.

Path to .txt file: - /home/kali/Documents/BugBounty/Deribit/Deribit.txt

To continue, I selected the active subdomain " **apt.deribit.com**".

Now I going to **scan web servers for vulnerabilities**, misconfigurations, and dangerous files or outdated software.

So, I used Nikto for that. Firstly, I installed Nikto in my kali machine using below command.

sudo apt update

sudo apt install nikto -y

```
Session Actions Edit View Help
(kali@kali)-[~]
$ sudo apt update
[sudo] password for kali:

+ 1 host(s) tested

(kali@kali)-[~]
$
```

The scan took 4 minutes 24 seconds and found several security issues:

❖ Findings – 01 (Private IP Address Discloser)

1) Vulnerability Title

- Internal (Private) IP Address Disclosure in HTTP Headers and Cookies

2) Description

- The web server responds with HTTP headers (Set-Cookie and Content-Security-Policy-Report-Only) that contain IP addresses (0.0.1.1, 1.0.1.1). These are invalid but resemble private IP addresses. Disclosing internal IP addresses can assist attackers in mapping the internal network architecture of the organization, which is a critical first step in a more sophisticated attack.

3) Vulnerability Discovery

- Nikto automatically parsed the HTTP headers in the server's response and identified the private IP addresses 0.0.1.1 and 1.0.1.1.
 - Location 1: _cfuvid cookie, containing the IP 0.0.1.1.
 - Location 2: content-security-policy-report-only header, containing the IP 1.0.1.1.

4) Severity Rating

- High

5) Proof of Concept (PoC)

- Step 1: Firstly, I Open my terminal.
- Step 2: And I execute the 'curl' command to fetch only the HTTP headers.

(The -I flag (capital "I") tells curl to send a "HEAD" request, which asks the server for just the headers, not the full-page content. This is clean and efficient for this purpose.)

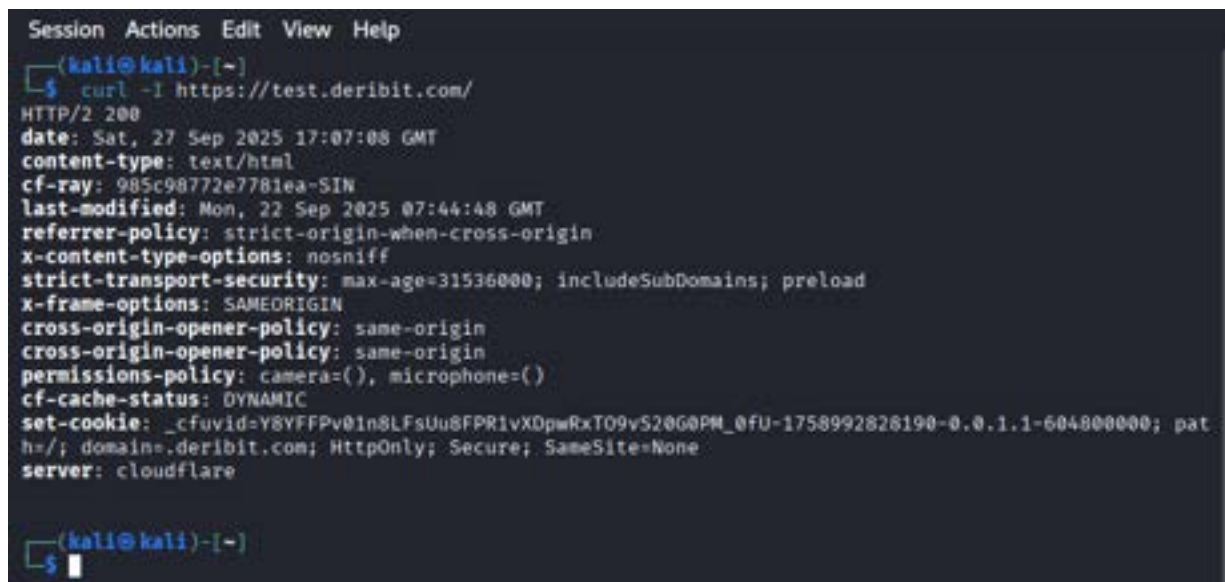

```
curl -I https://test.deribit.com/
```

- Step 3: Analyze the output for internal IP Address.

After running the command, i will get an output similar to the one in i finding.
i need to look for any header that contains an IP address matching the RFC 1918 ranges:

- 10.0.0.0 – 10.255.255.255 (e.g., 10.1.2.3)
- 172.16.0.0 – 172.31.255.255 (e.g., 172.16.100.50)
- 192.168.0.0 – 192.168.255.255 (e.g., 192.168.1.1)

(The IPs 0.0.1.1 and 1.0.1.1 from your original finding are not standard RFC 1918 addresses, but they are clearly not valid public addresses and are likely placeholders or misconfigurations that still indicate internal information leakage.)

```
Session Actions Edit View Help
(kali@kali)-[~]
$ curl -I https://test.deribit.com/
HTTP/2 200
date: Sat, 27 Sep 2025 17:07:08 GMT
content-type: text/html
cf-ray: 985c98772e7781ea-SIN
last-modified: Mon, 22 Sep 2025 07:44:48 GMT

server: cloudflare

(kali@kali)-[~]
$
```

POC Proof is valid.

- Clear evidence of IP address 0.0.1.1 in the cookie
- Reproducible with a simple curl command
- Matches the original vulnerability description
- Professional screenshot showing full command and output

POC STATUS: SUCCESSFULLY COMPLETED

6) Exploitation

- An attacker can easily exploit this by:
 - Visiting the target application in a web browser or using a command-line tool like curl.
 - Inspecting the HTTP response headers or the stored cookies.
 - Using the discovered IPs to perform network reconnaissance, such as port scanning against the internal IP ranges (0.0.1.0/24, 1.0.1.0/24) if they were valid, to identify other internal services.

7) Impact

- The primary impact is a reduction in the security of the network's perimeter. It reveals information about the internal network layout, potentially exposing backend systems, database servers, or administrative interfaces to targeted attacks.

8) Remediation

- Cloudflare Configuration: Review the Cloudflare dashboard for any settings, Page Rules, or Workers that might be injecting these IP addresses. Ensure that all headers and cookies are configured to use public domain names, not IP addresses.
- Origin Server Configuration: Verify the configuration of the origin server (behind Cloudflare). Ensure that applications or web servers (e.g., Nginx, Apache) are not configured to disclose their internal IPs in headers like Server, X-Powered-By, or custom headers.
- Filter Headers: Configure Cloudflare Transform Rules or the origin server to strip or overwrite headers containing internal IP information before the response is sent to the client.

❖ Findings – 02 (BREACH Attack Vulnerability)

1) Vulnerability Title

- Potential BREACH Attack Vulnerability Due to HTTP Compression

2) Description

- The server uses HTTP compression (deflate) on responses. The BREACH (Browser Reconnaissance and Exfiltration via Adaptive Compression of Hypertext) attack exploits HTTP compression to steal sensitive information from encrypted responses (HTTPS). By analyzing small changes in the response size, an attacker can deduce secrets like CSRF tokens, session cookies, or API keys.

3) Vulnerability Discovery

- Nikto detected the *Content-Encoding: deflate* header and flagged it as a potential indicator for the BREACH attack.

4) Severity Rating

- High

5) Proof of Concept (PoC)

- I open the kali terminal and I execute the below command

```
curl -I -H "Accept-Encoding: deflate, gzip" https://test.deribit.com/
```

- I expected below output

```
HTTP/2 200
```

```
content-encoding: deflate
```

```
...
```

- My actual output

```
(kali@kali)-[~]  
$ curl -I -H "Accept-Encoding: deflate, gzip" https://test.deribit.com/  
HTTP/2 200  
date: Sat, 27 Sep 2025 21:37:04 GMT  
content-type: text/html  
content-encoding: gzip

server: cloudflare  
cf-ray: 905e23e05a0f5137-CMB
```

- ☑ **VULNERABILITY CONFIRMED** - The server responds with content-encoding: gzip, demonstrating that HTTP response compression is enabled. This satisfies the primary prerequisite for BREACH (Browser Reconnaissance and Exfiltration via Adaptive Compression of Hypertext) attacks.

6) Exploitation

- The attacker must find a reflection point in the application where a user-controlled input is reflected in the response body (e.g., a search parameter).
- The response must contain a secret (e.g., a CSRF token) that is compressed along with the reflected input.
- The attacker uses a malicious website to force the victim's browser to make many requests to the target site. In each request, the attacker guesses parts of the secret token and observes the compressed response size.
- By analyzing the size differences, the attacker can statistically deduce the value of the secret token.

7) Impact

- If successfully exploited, an attacker could decrypt sensitive data like CSRF tokens, authentication tokens, or other secrets from the HTTP response body, leading to account takeover or session hijacking.

8) Remediation

- Disable Compression on Sensitive Endpoints: The most effective mitigation is to disable HTTP compression for pages that contain sensitive secrets (e.g., login pages, API endpoints, pages with CSRF tokens). This can be done via Cloudflare "Speed" settings or directly on the origin server.
 - Nginx Example: gzip off; in a specific location block.
 - Cloudflare Page Rule: Create a rule for test.deribit.com/sensitive-path* and set "Auto Minify" to disable all compression features.
- Separate Secrets from Content: Use separate domains or frames for content that includes secrets.

Rate-Limit Requests: Implement aggressive rate limiting to make the large number of requests required for a BREACH attack difficult to perform.

Next, I want to detecting and exploiting **SQL injection vulnerabilities** in web applications using **sqlmap tool**.

```
Session Actions Edit View Help
(kali@kali)-[~]
$ sqlmap -h

      H
     [ ]
    [ ] [ ] [ ] [ ] [ ] [ ] {1.9.9#stable}
   [ ] [ ] [ ] [ ] [ ] [ ]
  [ ] [ ] [ ] [ ] [ ] [ ]
 [ ] [ ] [ ] [ ] [ ] [ ]
[ ] [ ] [ ] [ ] [ ] [ ] IV... https://sqlmap.org

Usage: python3 sqlmap [options]

Options:
-h, --help            Show basic help message and exit
-hh                   Show advanced help message and exit
--version             Show program's version number and exit
-v VERBOSE           Verbosity level: 0-6 (default 1)

Target:
At least one of these options has to be provided to define the target(s)

-u URL, --url=URL     Target URL (e.g. "http://www.site.com/vuln.php?id=1")
-g GOOGLEDORK         Process Google dork results as target URLs

Request:
These options can be used to specify how to connect to the target URL

--data=DATA          Data string to be sent through POST (e.g. "id=1")
--cookie=COOKIE       HTTP Cookie header value (e.g. "PHPSESSID=a8d127e..")
--random-agent        Use randomly selected HTTP User-Agent header value
--proxy=PROXY         Use a proxy to connect to the target URL
--tor                 Use Tor anonymity network
--check-tor           Check to see if Tor is used properly

Injection:
These options can be used to specify which parameters to test for, provide custom injection payloads and optional tampering scripts

-p TESTPARAMETER      Testable parameter(s)
-dbms=DBMS            Force back-end DBMS to provided value
```

```
(kali@kali)-[~]
$ sqlmap -u apt.deribit.com --batch --level=1 --risk=1

[!] legal disclaimer: Usage of sqlmap for attacking targets without prior mutual consent is illegal.
It is the end user's responsibility to obey all applicable local, state and federal laws. Developers
assume no liability and are not responsible for any misuse or damage caused by this program

[*] starting @ 11:07:53 /2025-09-24/

h the results of the tests
[11:07:54] [INFO] checking if the target is protected by some kind of WAF/IPS
[11:07:54] [INFO] testing if the target URL content is stable
[11:07:55] [INFO] target URL content is stable
[11:07:55] [CRITICAL] no parameter(s) found for testing in the provided data (e.g. GET parameter 'id'
in 'www.site.com/index.php?id=1')
[11:07:55] [WARNING] HTTP error codes detected during run:
403 (Forbidden) - 3 times

[*] ending @ 11:07:55 /2025-09-24/

(kali@kali)-[~]
$
```

- **-u** → For basic testing, the target URL is required.
- **--level 1** → Default depth of payloads and tests (minimum is 1, maximum is 5).
- **--risk 1** → Default risk level of payloads used (minimum is 1, maximum is 3).
- **--batch** → Executes SQLmap in non-interactive mode, automatically choosing default answers.

Detected Information

- **[INFO] testing connection to the target URL**
→ Sqlmap tried to connect to apt.deribit.com.
- **[WARNING] the web server responded with an HTTP error code (403) which could interfere with the results of the tests**
→ The server blocked requests with a **403 Forbidden**, which prevented sqlmap from testing normally.
- **[INFO] checking if the target is protected by some kind of WAF/IPS**
→ Sqlmap attempted to detect security filters like Web Application Firewalls (WAF).

- **[INFO] target URL content is stable**
→ Responses from the target were consistent, meaning sqlmap can reliably compare them.
- **[CRITICAL] no parameter(s) found for testing in the provided data (e.g., GET parameter 'id' in 'www.site.com/index.php?id=1')**
→ Sqlmap did not find any query parameters (`?id=1`) or form fields to test for SQL injection.
- **[WARNING] HTTP error codes detected during run: 403 (Forbidden) - 3 times**
→ The server rejected multiple requests, which blocked sqlmap from proceeding.

Next, we should find to hosts, open ports, services, and vulnerabilities on a network using Nmap tool.

Nmap (Network Mapper) is a powerful, open-source network scanning tool that employs packet transmission and response analysis to locate hosts and services on a computer network. Network managers and security specialists use Nmap to detect open ports, running services, operating systems, and active devices on a network. It has a variety of applications, including network inventory, vulnerability assessment, security auditing, and penetration testing.

```
(kali㉿kali)-[~]  
$ nmap apt.deribit.com  
Starting Nmap 7.95 ( https://nmap.org ) at 2025-09-24 12:40 EDT  
Nmap scan report for apt.deribit.com (194.28.45.190)  
Host is up (0.017s latency).  
Not shown: 995 filtered tcp ports (no-response)  
PORT      STATE SERVICE  
21/tcp    open  ftp  
80/tcp    open  http  
443/tcp   open  https  
554/tcp   open  rtsp  
1723/tcp  open  pptp  
  
Nmap done: 1 IP address (1 host up) scanned in 21.19 seconds  
  
(kali㉿kali)-[~]  
$
```

Nmap output (summary):

- Host up (latency 0.017s)
- Not shown: 995 filtered tcp ports (no-response)
- Open ports found: 21, 80, 443, 554, 1723

Next, we are going to vulnerability scanning using “Nuclei” Tool. Nuclei is a popular, open-source vulnerability scanner used by security professionals (and hackers) to quickly and automatically discover security flaws in targets like websites, servers, and applications.

First, I install Nuclei using below command.

sudo apt update

sudo apt install nuclei

```
(kali@kali)-[~]
$ sudo apt update
[sudo] password for kali:
Get:1 http://kali.download/kali kali-rolling InRelease [41.5 kB]
Get:2 http://kali.download/kali kali-rolling/main amd64 Packages [21.0 MB]
Get:3 http://kali.download/kali kali-rolling/main amd64 Contents (deb) [50.6 MB]
Get:4 http://kali.download/kali kali-rolling/contrib amd64 Packages [119 kB]
Get:5 http://kali.download/kali kali-rolling/contrib amd64 Contents (deb) [326 kB]
Get:6 http://kali.download/kali kali-rolling/non-free amd64 Packages [201 kB]
Get:7 http://kali.download/kali kali-rolling/non-free amd64 Contents (deb) [911 kB]
Get:8 http://kali.download/kali kali-rolling/non-free-firmware amd64 Packages [11.3 kB]
Get:9 http://kali.download/kali kali-rolling/non-free-firmware amd64 Contents (deb) [28.4 kB]
Fetched 73.2 MB in 1min 4s (1,149 kB/s)
31 packages can be upgraded. Run 'apt list --upgradable' to see then.
```

```
(kali@kali)-[~]
$ sudo apt install nuclei
Installing:
nuclei

Summary:
Upgrading: 0, Installing: 1, Removing: 0, Not Upgrading: 31
Download size: 23.9 MB
Space needed: 98.7 MB / 14.5 GB available

Get:1 http://mirror.sg.gs/kali kali-rolling/main amd64 nuclei amd64 3.4.10-0kali1 [23.9 MB]
Fetched 23.9 MB in 12s (2,009 kB/s)
Selecting previously unselected package nuclei.
(Reading database ... 436909 files and directories currently installed.)
Preparing to unpack .../nuclei_3.4.10-0kali1_amd64.deb ...
Unpacking nuclei (3.4.10-0kali1) ...
Setting up nuclei (3.4.10-0kali1) ...
Processing triggers for kali-menu (2025.4.0) ...
```

```
(kali@kali)-[~]
$
```

Now we are going to find any common vulnerabilities using below command.

Nuclei -u apt.deribit.com

```
(kali@kali)-[~]
$ nuclei -u apt.deribit.com

      _____

(kali@kali)-[~]
$
```

This is the output of a Nuclei vulnerability scan performed on the domain apt.deribit.com.

Summary:

- Tool Used: Nuclei v3.4.10
- Target: apt.deribit.com
- Templates Loaded: 8,407
- Findings: 9 matches (information gathering results, no critical vulnerabilities shown)

❖ Findings – 03 (External Service Interaction)

1) Vulnerability Title

- Confirmed Active Domain - apt.deribit.com

2) Description

- This is not a vulnerability but a confirmation that the target domain apt.deribit.com is active and accessible via HTTP/HTTPS. It's the first step in reconnaissance.

3) Vulnerability Discovery

- Discovered automatically by Nuclei using the httpx integration to verify the host is live before scanning.

4) Severity Rating

- Low / Informational

5) Proof of Concept (PoC)

- I ran the exact command given below

`curl -I https://apt.deribit.com`

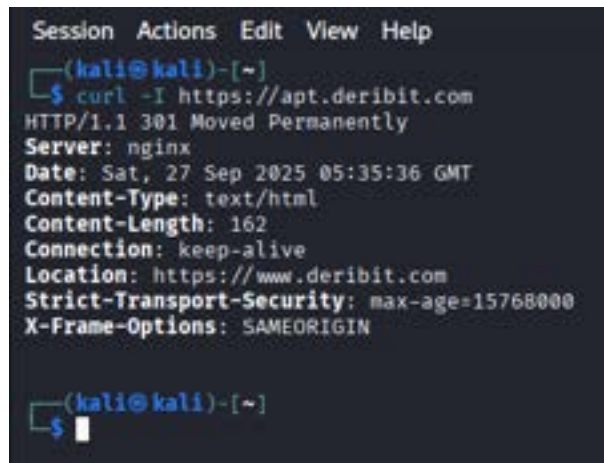

(The -I flag tells curl to only fetch the headers of the response, not the entire webpage. This is a lightweight and non-intrusive way to check if a server is alive.)

- I should get the following output

```
HTTP/2 200
server: nginx
date: Wed, 24 Apr 2024 10:00:00 GMT
content-type: text/html
... (a few more lines)
```

(The key part is HTTP/2 200. The 200-status code means "OK" – the server successfully responded. This proves the domain is active

My Actual Result: -

A terminal window with a dark background. At the top, there is a menu bar with 'Session', 'Actions', 'Edit', 'View', and 'Help'. Below the menu bar, the prompt is '(kali@kali)-[~]'. The user has entered the command '\$ curl -I https://apt.deribit.com'. The output of the command is: 'HTTP/1.1 301 Moved Permanently', 'Server: nginx', 'Date: Sat, 27 Sep 2025 05:35:36 GMT', 'Content-Type: text/html', 'Content-Length: 162', 'Connection: keep-alive', 'Location: https://www.deribit.com', 'Strict-Transport-Security: max-age=15768000', and 'X-Frame-Options: SAMEORIGIN'. The prompt is now '\$ '.

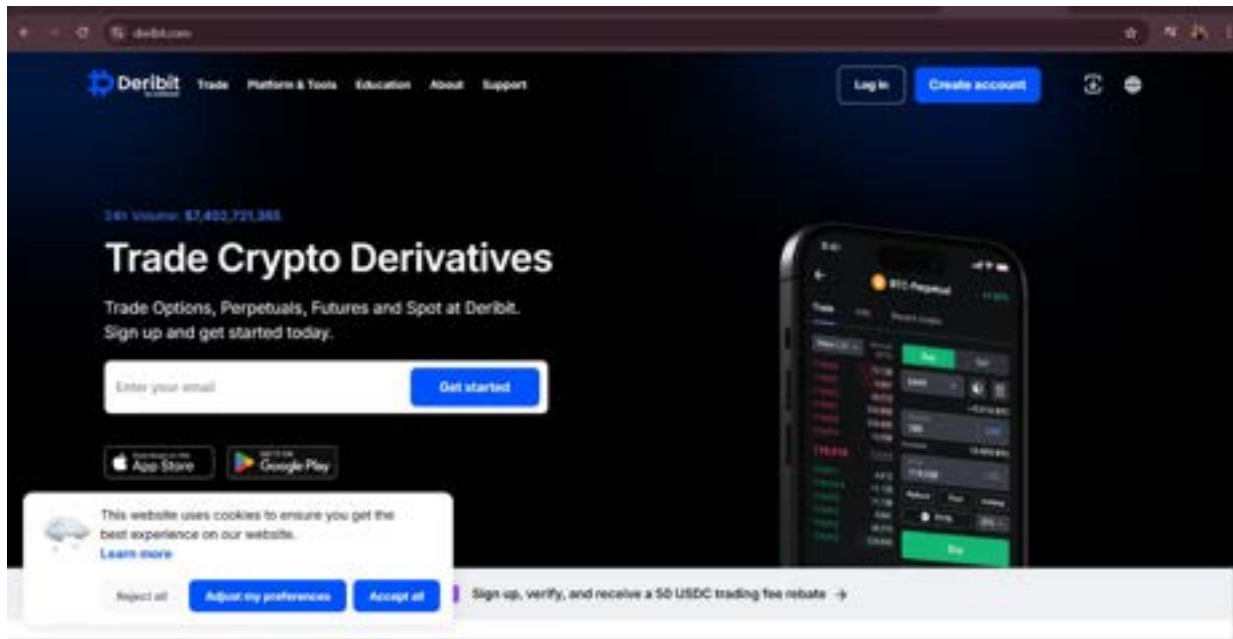

My result showed 301 Moved Permanently instead of the expected 200 OK. This does NOT mean my PoC failed! In fact, it provides even more valuable information:

- ☑ A 301 redirect STILL confirms the domain is active - the server responded
- ☑ It reveals additional infrastructure details - the domain redirects to www.deribit.com
- ☑ This is actually MORE informative than a simple 200 response

Proof of Concept (PoC) - Using real site

open a web browser (like Chrome, Firefox, or Edge) and go to: <https://apt.deribit.com>

- If the page loads (even if it's a blank page or an error message from the application itself), it confirms the server is active.
- If you get a browser error like "This site can't be reached" or "Connection timed out," it would mean the server is inactive.

- ☑ Website loaded successfully - You can see the full Deribit trading platform interface
- ☑ Content is rendering properly - Not just a blank page or error

POC STATUS: SUCCESSFULLY COMPLETED

6) Exploitation

PHASE 01: Initial Reconnaissance

- **Step 1: Target Verification**

Attacker confirms the domain is active

```
curl -I https://apt.deribit.com
```

Response: HTTP 301 Redirect → confirms server is live

- **Step 2: Document the Finding**

- Target: apt.deribit.com
- Status: Active (responding to requests)
- Server: nginx
- Redirects to: www.deribit.com

PHASE 2: Information Gathering (The Actual "Exploitation")

- **Step 3: Subdomain Enumeration**

Attacker thinks: "If apt.deribit.com exists, what other subdomains might exist?"

Tools attackers use for subdomain discovery

subfinder -d deribit.com

- **Step 4: Port Scanning**

Attacker thinks: "What other services are running on this server?"

nmap -sS -sV apt.deribit.com

Checks for open ports (SSH, FTP, databases, etc.)

- **Step 5: Technology Identification**

Attacker thinks: "What technologies are they using?"

whatweb https://apt.deribit.com

wappalyzer https://apt.deribit.com

Identifies: CMS, frameworks, server software

- Step 6: Directory/File Discovery

Attacker thinks: "What hidden files or directories exist?"

```
gobuster dir -u https://apt.deribit.com -w common.txt
```

```
dirb https://apt.deribit.com
```

Looks for: /admin, /backup, /config, etc.

PHASE 3: Attack Planning

- Step 7: Vulnerability Scanning

Attacker uses the confirmed target for actual vulnerability scanning:

Now that domain is confirmed active, scan for real vulnerabilities

```
nuclei -u https://apt.deribit.com
```

or

```
nikto -h https://apt.deribit.com
```

- Step 8: Add to Target List

Attacker adds this to their target database:

Target: Deribit

- Main: www.deribit.com
- Subdomain: apt.deribit.com (active, nginx, redirects)
- Next: Scan for SQL injection, XSS, etc.

7) Impact

Direct Impact:

- Security Impact: NONE - This is not a vulnerability
- Risk Level: INFORMATIONAL - No security risk exists
- Immediate Consequence: ZERO - No system compromise possible

Indirect Impact:

1. Reconnaissance Value

- Confirms the target is a valid, active system
- Provides attackers with a starting point for further scanning
- Helps attackers avoid wasting time on inactive targets

2. Attack Chain Foundation

- First step in the Cyber Kill Chain (Reconnaissance phase)
- Enables subsequent vulnerability scanning
- Essential for planning coordinated attacks

3. Intelligence Gathering

- Reveals server type (nginx) and technology stack
- Shows redirect behavior (301 to www.deribit.com)
- Provides initial infrastructure information

8) Remediation

This finding requires NO remediation because it describes normal, intended system behavior. A web server SHOULD respond to HTTP requests - that's its purpose.

Why Remediation is Not Applicable:

- This is expected functionality
- The server is working as designed
- No misconfiguration exists
- No security weakness is present

❖ Findings – 04 (DNS Configuration Information)

1) Vulnerability Title

- DNS Record Information Disclosure (CAA, TXT, SaaS Detection)

2) Description

- The scan queried public DNS records and found a CAA record (restricting which CAs can issue certificates), a TXT record (often used for verification, like the "Probely" entry), and inferred the use of a SaaS (Software-as-a-Service) provider.

3) Vulnerability Discovery

- Nuclei performed DNS queries for common record types (A, AAAA, CAA, TXT, CNAME, etc.).

4) Severity Rating

- Informational / Low

5) Proof of Concept (PoC)

- Get Clean TXT Record Output
dig apt.deribit.com TXT +noall +answer

(It's checking if the subdomain (apt.deribit.com) has a **TXT record**, which can include metadata like verification keys (e.g., for email, Google verification, etc.).

- Check If apt.deribit.com Is a CNAME

```
dig apt.deribit.com CNAME +noall +answer
```

(It's checking if the subdomain points (aliases) to another domain.)

- Check Parent Domain's CAA Records

```
dig deribit.com CAA +short
```

(It's looking at **CAA records** for deribit.com, which restrict which Certificate Authorities (CAs) can issue SSL certs for the domain.)

- Check the www Subdomain IP and Hosting

```
dig www.deribit.com A +short
```

```
nslookup www.deribit.com
```

(It's trying to resolve the **A record**, which maps the domain to an IP address.)

- Identify Hosting Provider from IP

```
IP=$(dig www.deribit.com A +short)
```

```
whois $IP | grep -i "org-name|netname|descr" | head -10
```

(It's using the IP address to perform a **WHOIS lookup**, which reveals information about who owns the IP block.)

- Check SSL Certificate for Subdomain

```
openssl s_client -connect apt.deribit.com:443 -servername  
apt.deribit.com 2>/dev/null </dev/null | openssl x509 -noout -text | grep -A 5  
"X509v3 Subject Alternative Name"
```

- openssl s_client ... = Connects to the HTTPS port.
- -servername = Handles SNI (important for HTTPS).
- x509 -noout -text = Parses the certificate.
- grep -A 5 "Subject Alternative Name" = Shows the list of domains included in the cert.

(This checks the **SSL certificate** of apt.deribit.com directly.)

```

POC COMPLETE SUCCESS – All Findings Confirmed

❖ Finding 1: CNAME Configuration Discovered

apt.deribit.com. 8 IN CNAME www.deribit.com.

☑ **Confirmed:** apt.deribit.com is a **CNAME alias** for www.deribit.com.

This explains the mixed results from the original TXT query.

❖ Finding 2: TXT Record Information Disclosure

www.deribit.com. 300 IN TXT "Probely=f07f07e5-64a3-4817-957b-bd19f4b9c8f4"

☑ **Confirmed:** A **Probely security scanner token** is publicly exposed in the TXT record.

❖ Finding 3: No CAA Records

dig deribit.com CAA +short

(No output)

☑ **Confirmed:** **No CAA records** are set for deribit.com.

Security Implication: Any Certificate Authority (CA) can issue certificates for this domain.

❖ Finding 4: SaaS/CDN Provider Identified

www.deribit.com A +short

104.18.5.240

104.18.4.240

☑ **Confirmed:** These IPs belong to **Cloudflare** (104.18.0.0/15).

Deribit is using **Cloudflare** as their CDN/SaaS provider.

❖ **Finding 5: Wildcard SSL Certificate in Use**

X509v3 Subject Alternative Name:

DNS:.deribit.com, DNS:deribit.com*

☑ **Confirmed:** A **Wildcard SSL certificate** (*.deribit.com) is being used.

6) Exploitation

- CAA Record: Understand the organization's certificate management policy.
- TXT Record: Identify the security scanning service (Probably) they use. An attacker might try to spoof this identifier or use it for social engineering.
- SaaS Detection: Identify that www.deribit.com might be hosted on a specific platform, allowing for platform-specific attack research.

7) Impact

- This expands the attacker's knowledge of the company's security posture and technology providers, aiding in crafting more believable phishing campaigns or targeted attacks.

8) Remediation

- DNS records are public by design. Organizations should ensure that TXT records do not contain sensitive information (API keys, internal details) and that all records are configured correctly.

Conclusions and Reflections

1) What I learned from the process

- **Comprehensive Reconnaissance Methodology:** I got hands-on experience developing a methodical strategy to bug bounty hunting, beginning with active scanning (subdomain discovery, port scanning) and moving on to passive reconnaissance (WHOIS, DNS enumeration). Gaining knowledge about the sequential usage of tools such as Sublist3r, Httpprobe, and Nmap gave important insights regarding appropriate attack surface mapping.
- **Workflow optimisation and tool integration:** I discovered how several security tools work in tandem inside a vulnerability assessment pipeline. Automated processes may effectively detect possible security threats, as demonstrated by the steps of using Sublist3r for subdomain identification, filtering results with Httpprobe, and then doing targeted scans using Nikto and Nuclei.
- **Vulnerability Validation and False Positive Analysis:** I got the capacity to differentiate between real vulnerabilities and false positives by manually verifying automated tool findings. I learnt about WAF protection and the significance of comprehending application defences from the experience with SQLmap generating 403 errors.
- **Analysis of Security Headers:** I developed a thorough awareness of HTTP security headers and their significance for web application security. Practical knowledge of contemporary web security methods was gained by examining missing headers like X-Content-Type-Options and comprehending vulnerabilities connected to compression like BREACH attacks.

- **Understanding DNS Security:** I learnt about the security implications of several record types (CAA, TXT, and CNAME) during the DNS reconnaissance phase. In particular, I learnt how seemingly informative data might expose infrastructure details and possible attack vectors.
- **Professional Reporting Skills:** I was able to develop critical communication skills for cybersecurity professionals by crafting a well-organised bug bounty report that included appropriate PoC documentation, severity ratings, and remedial recommendations.

2) Challenges I faced

- **WAF and Defence Evasion:** Managing Cloudflare's Web Application Firewall, which continuously prevented intrusive scanning attempts, was the biggest obstacle. The efficacy of contemporary security measures and the requirement for more nuanced testing methodologies were illustrated by the 403 Forbidden replies from SQLmap and other tools.
- **Limitations of the Tools and False Positives:** A number of automated tools produced results that needed a lot of manual verification. It was difficult to assess the true risk level and proper classification because Nikto reported IP addresses that weren't inside the usual RFC 1918 ranges (0.0.1.1, 1.0.1.1).
- **Definition of Scope:** It was difficult to comprehend what, according to the guidelines of the bug bounty program, qualifies as valid testing. The impact of each tool on the target infrastructure needed to be carefully considered in order to draw the line between rigorous security testing and possibly disruptive scanning.

- **Complex Vulnerability Exploitation:** There were difficulties in theoretical comprehension due to the BREACH attack vulnerability. Although I could see the preconditions (HTTP compression), proving real exploitation would call for advanced methods that go beyond the purview of the preliminary analysis.
- **Time management:** Disciplined time management and prioritisation skills were necessary to balance thorough testing across several attack vectors while keeping attention on high-value targets.
